

# Predicting Cohesive Comprehension Based on Individual Differences and Genre Effects

Authors: **Lauren E. Flynn**, Joseph P. Magliano, Katherine S. McCarthy,  
Danielle S. McNamara, & Laura K. Allen

The Society for  
Text & Discourse

Hi everyone, I'm Lauren from the University of New Hampshire and welcome to my presentation on "Predicting Cohesive Comprehension Based on Individual Differences and Genre Effects."

## successful text comprehension

when a reader has constructed a  
*coherent* & meaningful mental  
representation of a text

## FACTS

(McNamara & Magliano, 2009; Magliano et al., 1999)

Readers have successfully comprehended a text when they have constructed both a *coherent* and meaningful mental representation of it.

Coherence-building processes occur when readers, not only process and understand the individual facts of a text, but expand on it by generating inferences and/or elaborations from their own life experiences or prior knowledge.

However, it should be noted that coherence is a different concept than cohesion.

## successful text comprehension

when a reader has constructed a  
*coherent* & meaningful mental  
representation of a text

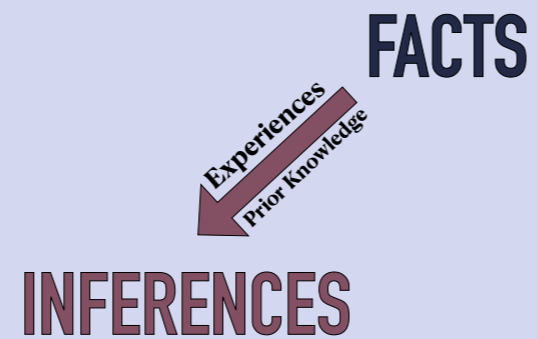

**FACTS**

(McNamara & Magliano, 2009; Magliano et al., 1999)

## successful text comprehension

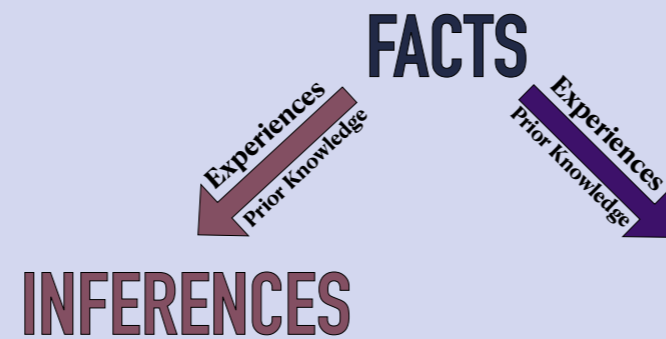

when a reader has constructed a  
*coherent* & meaningful mental  
representation of a text

(McNamara & Magliano, 2009; Magliano et al., 1999)

Whereas coherence is a property uniquely between the reader and text, cohesion is a linguistic property of a text.

Coherence represents a holistic understanding where one makes meaningful connections or interpretations between ideas of the text. However, cohesion is more representative of how connected words and sentences are within discourse.

Coherence is also a necessity for comprehension, whereas cohesion can only aid in it. Therefore, these concepts are NOT mutually exclusive. For example, my to-do list may be cohesive but not very coherent to anyone else reading it.

## **think-aloud procedures**

examines coherence-  
building processes  
while reading

In order to examine the coherence-building process while reading, think-aloud procedures are used where readers are stopped at specific target sentences to report their thoughts before continuing on to read.

# think-aloud procedures

examines coherence-  
building processes  
while reading

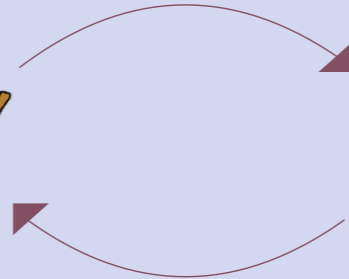

**report  
thoughts**

# think-aloud procedures

building processes  
while reading

**report  
thoughts**

## **cohesion & think-alouds**

(Allen et al., 2016; 2015)

Think-aloud responses can then be analyzed for cohesion.

The cohesion of readers' think-alouds depends on the reader successfully developing coherent representations while reading.

This is then used to measure readers' coherence of the text and has been previously found to be associated with certain individual differences such as reading skills and vocabulary knowledge.

## **cohesion & think-alouds**

## **individual differences**

comprehension performance tied to working memory & reading skill

Many individual differences have been linked to a reader's likelihood of successfully developing coherent representations during reading and thus examining individual differences in relation to think-aloud properties may provide insight on how these differences manifest themselves during the reading process.

2 individual differences that have previously been found to be connected with text comprehension are working memory and reading skill, both of which are positively correlated with comprehension.

## **current study**

examines how cohesion manifests across different text genres

The current study examines how cohesion manifests across different text genres. The genres used here were history and science.

We also examined how individual differences manifest within reader think-alouds: again, focusing specifically on working memory and reading skills.

## method

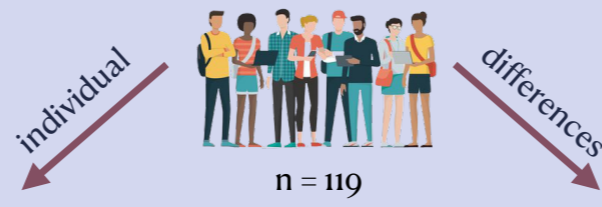

n = 119

119 students completed assessments of reading skills (using the Gates-Macginitie Reading Test) and working memory (the Operational Span Task).

Students then read both a history (either on the Civil War or labor workers) and science (either on evolution of erosion) text.

## **method**

Participants read each text line-by-line on computers and were asked to report their thoughts after each sentence.

Think-aloud responses were analyzed for cohesion using, the natural language processing tool, TAACO.

We then looked at 3 different levels of cohesion: sentence, paragraph, and synonym level.

| Adjacent Paragraph Noun Overlap |                |         |       |               |         |       |
| Adjacent Paragraph Verb Overlap |                |         |       |               |         |       |

We first examined correlations between individual differences and cohesion. Only one cohesion variable had a significant correlation with working memory: adjacent paragraph verb synonym overlap. However, all but two of the cohesion variables were significantly related to reading skill. These correlations suggest that the connections observed, overall, in readers' think-aloud responses are more strongly related to their reading skill than their scores on the working memory task.

We then examined whether these correlations differed by genre. We found significant, weak negative relationships between cohesion and working memory for history texts, but not for science. We also found, significant, very weak to weak positive correlations between cohesion and reading skill for both the history and science texts, albeit with stronger relations within the history genre. These results suggest that texts may have subtle differential relations to coherence-building processes across different genres.

| synonym cohesion   |                |

The relationships between genre, individual differences, and cohesion were then examined using linear mixed effects models. These are the highest interaction chi-squares reported at each of the 3 levels of cohesion: sentence, paragraph, and synonym. Significant interaction effects between genre and working memory were found at each level of cohesion. However, in line with our correlation results, no interaction effects were found with reading skills.

## discussion

HISTORY

SCIENCE

Overall, our correlation analyses indicated that think-aloud cohesion was significantly correlated with reading skill for both history and science texts, indicating that skilled readers generated more explicit connections amongst the thoughts generated in their think-aloud responses. This is in line with prior work that has found significant relations between reading skill and think-aloud cohesion.

However, working memory was only related to think-aloud cohesion for history texts, and the relation was negative rather than positive. Thus, individuals with higher working memory capacity may establish fewer explicit connections during reading, particularly for history texts.

## **discussion**

The results discussed suggest that these individual differences may operate in different ways across varied contexts that may have differential demands on skill and capacity. It also suggests that reading skill may be more related to cohesive think-aloud responses than working memory. Therefore, since reading skill is a malleable skill (unlike working memory), this suggests that difficulties associated with coherence-building may be more easily remedied through reading strategy instruction. Future research is needed to explore reading strategy as an aid to coherence-building.

## **discussion**

individual differences are related to one's ability to  
comprehend texts across various contexts

## **discussion**

individual differences are related to one's ability to  
comprehend texts across various contexts

suggests reading skill may be more important for  
coherence-building processes than working memory
